Description

Set of integrated capacitor arrangements, in particular integrated grid capacitors

5

The invention relates to an integrated capacitor arrangement containing at least one circuitry-effective main capacitor.

- 10 From an integrated arrangement, individual components cannot be mechanically separated from one another without destroying the components. Layer application methods and layer patterning methods, inter alia, are used as fabrication techniques for integrated
- 15 arrangements.

A capacitor contains two electrodes opposite one another between which a dielectric is arranged. Examples of integrated capacitors are:

- 20 - so-called MIM capacitors (Metal Insulator Metal),
- stacked capacitors, also referred to as sandwich capacitors, or
- grid capacitors.

- 25 A capacitance is circuitry-effective if it is not only parasitic, i.e. actually undesired, but is also necessary for the functioning of the circuit arrangement. By way of example, circuitry-effective capacitors serve as:

- 30 - blocking or backup capacitor,
- part of a resonant circuit,
- charging capacitor, or
- for storing digital information.

- 35 In the fabrication of so-called BEOL capacitances (Back End of Line) or of a far BEOL capacitance in integrated form, considerable variations arise in the capacitance values. The variation results from geometry deviations on account of process inhomogeneities. The variations

occur within a semiconductor wafer, within a production batch and also between different production batches. If the capacitance value of a capacitor lies outside the predetermined specification limits, then the result is
5 a so-called loss of performance or even a loss of yield of the corresponding integrated circuit.

It is an object of the invention to specify a simple-to-fabricate set of capacitor arrangements whose
10 capacitance is as near as possible to a predetermined desired capacitance. In particular, the intention is to specify a set of grid capacitors.

This object is achieved by means of a set of capacitor
15 arrangements having the features specified in patent claim 1. Developments are specified in the subclaims.

The set according to the invention contains at least two integrated capacitor arrangements, which have been
20 produced in accordance with identical geometrical designs or layouts and which each contain a circuitry-effective main capacitor and at least one correction capacitor. One capacitor arrangement contains an electrically conductive connection between
25 the correction capacitor and the main capacitor, the connection having been produced after the production of the main capacitor of this capacitor arrangement. The other capacitor arrangement contains an electrically insulating interruption between the same correction
30 capacitor and the main capacitor, the interruption having been produced in accordance with the geometrical designs.

If corrections have to be carried out, for example,
35 only in the case of 20% of the capacitor arrangements fabricated, in order to achieve the desired capacitance, then the outlay decreases considerably compared with a correction possibility in which the

correction can be performed only by disconnection of capacitors. This is because, in the case of such a correction, capacitors would need to be locally disconnected in 80% of the capacitor arrangements.

5

In one development, the connection is produced in a simple manner by local heating, so that components in proximity to the connection are protected from an increased thermal loading. Moreover, permanent links
10 can be produced by local heating in a simple manner. Compared with the production of interruptions by local heating, links can be implemented by local heating at lower temperatures. The thermal loading is thus low, particularly during the production of a multiplicity of
15 links on a semiconductor wafer.

The local heating is carried out for example with the aid of a laser beam. This affords a possibility of increasing or decreasing the capacitance of the
20 circuitry-effective main capacitor through connection in parallel or in series with the correction capacitors. This correction possibility allows integrated capacitor arrangements with predetermined capacitance values to be produced in a simple manner.

25

In one development, the connection contains two interconnect sections which are spaced apart from one another and between which only a dielectric is arranged. The materials of the interconnect sections
30 and of the dielectric are chosen such that material warpages of the interconnect which penetrate through the dielectric arise during the heating. By way of example, it is possible here to utilize the otherwise undesirable "spiking" for producing an electrical
35 connection. In an alternative configuration, the dielectric contains doping atoms which change the conductivity of the dielectric during the heating. Activation of the doping atoms is an expression that is

also used in this context. However, there are also other possibilities for producing the connection, which is also referred to as an antifuse.

- 5 In a next development, the circuit arrangements contain at least one further correction capacitor, which is disconnected from the main capacitor or has been connected to the main capacitor.
- 10 The development is based on the consideration that the capacitance values of integrated capacitors that are actually to be constructed identically vary around a desired value both downward and upward. Corrections can be restricted to a minimum if it is both possible to
- 15 correct the capacitance value toward larger capacitance values and possible to correct it toward smaller capacitance values. The further correction capacitor affords this second correction possibility in comparison with the abovementioned correction capacitor
- 20 with the capacitors connected in parallel.

In one development, a further interruption for disconnecting the further correction capacitor is produced by local heating. The local heating can be carried out,

25 for example, with the aid of a laser beam or with the aid of a current surge through an interconnect constriction.

In another development, dielectrics of the capacitors

30 are formed by a dielectric between metallization layers in which connection sections of connections to integrated semiconductor components of the integrated capacitor arrangement are situated. It is possible to use a different dielectric in the region of the

35 capacitor than in the remaining region between the metallization layers, e.g. a dielectric having a higher dielectric constant. Examples of such capacitors are stacked capacitors or grid capacitors. In other words,

the electrodes of a capacitor lie in more than two metallization layers. In the case of such capacitors, in one configuration, not only electrodes in the topmost metallization layer but also electrodes in
5 lower metallization layers are disconnected in terms of circuitry or added in terms of circuitry during the correction. The linking elements and interruptions for the lower electrodes are situated either in the lower metallization layer, so that it is necessary, for
10 example, to provide cutouts of corresponding depth for a laser beam, or in an upper metallization layer, to which connections from the lower metallization layer lead.

15 In another development, dielectrics of the capacitors have a thickness which is significantly less than the thickness of the dielectric between metallization layers. Examples of such capacitors are MIM capacitors. In other words, at least one electrode of the capacitor
20 lies outside a metallization layer.

In a next development, the capacitance of a correction capacitor amounts to less than $1/3$, less than $1/10$, less than $1/100$ or less than $1/1000$ of the capacitance
25 of a main capacitor. This measure means that fine trimming is possible. Thus, with possibilities for correction in the thousandths range, the capacitance values of two capacitor arrangements of the same integrated circuit arrangement can be coordinated with
30 one another very precisely. This is absolutely necessary for some applications.

The invention additionally relates to a set of grid capacitors with correction transverse electrodes.
35 Individual transverse electrodes of the grid capacitors also afford a possibility for correction of the capacitance during the production. The abovementioned

technical effects therefore apply particularly to the grid capacitors.

Exemplary embodiments of the invention are explained
5 below with reference to the accompanying drawings, in which:

figure 1 shows a plan view of an MIM capacitor arrangement,
10

figure 2 shows a plan view of a grid capacitor arrangement,

figure 3 shows a transverse electrode of a grid capacitor with two interruption possibilities,
15

figure 4 shows a transverse electrode of a grid capacitor with a continuous interruption possibility, and
20

figure 5 shows method steps for correcting the capacitance of an integrated capacitor.

25 Figure 1 shows a plan view of an MIM capacitor arrangement 10, which contains a main capacitor 12 connected to an electronic circuit and a plurality of disconnectable capacitors situated to the right of the main capacitor 12, of which only one disconnectable
30 capacitor 14 is illustrated. The dielectric is not illustrated in figure 1 for reasons of improved clarity.

In the capacitor arrangement 10, a plurality of
35 connectable capacitors are situated to the left of the main capacitor 12, of which one connectable capacitor 16 is illustrated in figure 1. The capacitors 12 to 16 are constructed identically except for their

longitudinal dimensions. The capacitors 12, 14 and 16 respectively contain a bottom electrode 18, 20 and 22 near the substrate and an electrode 24, 26 and 28 remote from the substrate. The bottom electrodes 18, 20 and 22 are longer than the respectively associated electrode 24, 26 and 28 remote from the substrate and project beyond the electrode 24, 26 and 28 remote from the substrate in the longitudinal direction on both sides, so that terminal regions for vertically running contacts 30 are produced at the bottom electrodes 18, 20 and 22 near the substrate.

The main capacitor 12 and the disconnectable capacitors 16 are electrically connected in parallel by interconnects 32 between the bottom electrodes 18, 20 and by interconnects 34 between the electrodes 24, 26 remote from the substrate. As seen geometrically, however, the disconnectable capacitors 14 are arranged in a row one behind the other. The interconnects 32 and 34 are situated in an upper metallization layer. A cutout 36 and 38 in an insulating material (not illustrated) which covers the interconnects 32 and 34 respectively leads to each interconnect 32 and 34. Through the cutouts 36 and 38, during a correction of the capacitance of the main capacitor 12, regions 40 and 42 of an interconnect 32 and 34, respectively, can be vaporized with the aid of a laser beam, thereby producing an interruption.

On the other hand, the connectable capacitors 16 can be electrically connected in parallel with the main capacitor 12 with the aid of interconnects 52 between the bottom electrodes 18, 22 and interconnects 54 between the electrodes 24, 28 remote from the substrate. Geometrically, however, the connectable capacitors 16 are arranged in a row. The interconnects 52 and 54 are also situated in an upper metallization layer.

Cutouts 56 and 58 lead through an insulating material (not illustrated) as far as linking regions 60 and 62 of the interconnects 52 and 54, respectively. The
5 linking regions 60, 62 form so-called antifuses, i.e. a connection possibility which forms a permanent electrically conductive connection between the sections of the interconnect 52 and an interconnect 54, respectively, upon the impingement of a laser beam.

10

The main capacitor 12 has a length L_a in the longitudinal direction of the capacitor arrangement 10, said length being greater than lengths L_b of the disconnectable capacitors 14 and lengths L_c of the
15 connectable capacitors 16. As a result, a capacitance $C(0)$ of the main capacitor 12 is also greater than a capacitance $C_m(I)$ of the capacitor 14. In this case I is a natural number for designating the last disconnectable capacitor 14. The disconnectable
20 capacitors not illustrated have capacitances $C_m(1)$ to $C_m(I-1)$ which are equal to the capacitance $C_m(I)$ in the exemplary embodiment explained.

The capacitance $C(0)$ of the main capacitor 12 is
25 likewise greater than the capacitance $C_p(1)$ of the connectable capacitor 16. The connectable capacitors not illustrated in figure 1 have capacitances $C_p(2)$ to $C_p(N)$, which are equal to the capacitance $C_p(1)$ or $C_m(I)$. In this case, N is a natural number for
30 designating the last connectable capacitor.

35

The correction of the capacitance of the capacitor arrangement 10 is explained in more detail below with reference to figure 5.

In another exemplary embodiment, there is only one disconnectable capacitor 14 and one connectable capacitor 16 to the right and left, respectively, of

the main capacitor 12. In a next exemplary embodiment there is only one or a plurality of connectable capacitors 16 and, respectively, only one or a plurality of disconnectable capacitors 14 beside the main capacitor 12. In a next exemplary embodiment the capacitances $C_m(1)$ to $C_m(I)$ of the capacitor arrangement 10 are different from one another. The capacitances $C_p(1)$ to $C_p(N)$ of the capacitor arrangement 10 can also be made different from one another.

Figure 2 shows a plan view of a grid capacitor arrangement 110, which contains a main capacitor 112 connected to a circuit and a plurality of disconnectable capacitors, one capacitor 114 of which is illustrated in figure 2. Furthermore, the grid capacitor arrangement 110 contains a plurality of connectable capacitors, one capacitor 116 of which is illustrated in figure 2. Only the upper electrode of the main capacitor 112 and of the capacitor 114 and of the capacitor 116 is respectively illustrated in figure 2. In the underlying metallization layers there are further electrodes having the same profile as the upper electrodes. In a first exemplary embodiment, the electrodes of a capacitor 112, 114 and 116 which are situated in the different metallization layers are connected among one another in each case by at least one vertical contact. Interconnects between capacitors 112, 114 and 116 are situated only in the upper metallization layer.

In the upper metallization layer, the main capacitor 112 contains two comb-shaped electrodes whose tines mesh with one another. By way of example, four transverse electrodes 120 to 126 lined up in a uniform grid dimension branch off from a longitudinal electrode 118. On a longitudinal electrode 128 opposite the longitudinal electrode 118, there are arranged,

transversely with respect to the longitudinal electrode 128, exactly as many transverse electrodes 130 to 136 as on the longitudinal electrode 118, i.e. four transverse electrodes 130 to 136 which extend into the interspaces between the transverse electrodes 120 to 126. A meandering interspace is thus formed between the transverse electrodes 120 to 126 and 130 to 136, said interspace being filled by a dielectric. The length of the meander of the main capacitor 112 shall again be L_a .

The disconnectable capacitors and the connectable capacitors are constructed like the main capacitor 112, but contain shorter longitudinal electrodes 140, 142, 144 and 146, respectively from each of which, by way of example, only two transverse electrodes 150 to 160 branch.

Situated between the longitudinal electrode 118 and the longitudinal electrode 142 of the capacitor 114 is a region 162, to which a cutout 164 leads from the surface of the integrated circuit. Situated between the longitudinal electrode 128 and the longitudinal electrode 140 of the capacitor 114 is a region 166, to which a further cutout 168 leads. Through the cutouts 164 and 168, it is possible, with the aid of a laser beam, to produce an interruption between the longitudinal electrodes 118 and 142 and the longitudinal electrodes 128 and 140 in the region 162 and 166, respectively. As a result, all the disconnectable capacitors 114 can be disconnected from the main capacitor 112. Situated between the further disconnectable capacitors are further regions 170 and 172, to which cutouts 174 and 176 lead, so that disconnection can also be effected at other locations.

A linking region 180 is situated between the longitudinal electrode 118 and the longitudinal

electrode 146 of the correction capacitor 116. A linking region 182 is situated between the longitudinal electrode 128 and the longitudinal electrode 144 of the capacitor 116. A cutout 184 and 186 leads to the linking region 140 and to the linking region 182, respectively. Through the cutouts 184 and 186, the linking regions 180 and 182 can be locally heated with the aid of a laser beam. During the local heating, a connection is produced between the longitudinal electrode 118 and the longitudinal electrode 146, and between the longitudinal electrode 128 and the longitudinal electrode 144. Electrically conductive connections to further connectable capacitors 116 can be produced with the aid of further linking regions 190, 192 to which cutouts 194 and 196, respectively, lead.

The meander of the main capacitor 112 has a length L_a , which is greater than a length L_b of a meander of the disconnectable capacitor 114 and a length L_c of a meander of the connectable capacitor 116. As a result, a capacitance $C(0)$ of the main capacitor 112 is greater than a capacitance $C_m(I)$ of the disconnectable capacitor 114. Further capacitances $C_m(1)$ to $C_m(I-1)$ of further disconnectable capacitors are equal to the capacitance $C_m(I)$. A capacitance $C_p(1)$ of the connectable capacitor 116 is equal to the capacitance $C_m(1)$. Capacitances $C_p(2)$ to $C_p(N)$ of the further disconnectable capacitors 116 are equal to the capacitance $C_p(1)$.

The correction of the capacitance of the circuit arrangement 110 is explained in more detail below with reference to figure 5.

In another exemplary embodiment, there are cutouts which lead into different metallization layers, for example to connection or interruption possibilities which are arranged offset with respect to connection or

interruption possibilities situated above or below the latter. In an alternative exemplary embodiment, linking regions or regions for interruptions are arranged in an upper metallization layer even though they also relate
5 to electrodes in lower metallization layers. Furthermore, the capacitances $C_m(1)$ to $C_m(I)$ or $C_p(1)$ to $C_p(N)$ of the capacitor arrangement 110 may have capacitances that differ from one another.

10 Figure 3 shows a transverse electrode 200 of a grid capacitor. The transverse electrode 200 has a region 202 over approximately one third of its length and a region 204 over approximately two thirds of its length. A cutout 206 leads to the region 202. A cutout 208
15 leads to the region 204. During the correction of the capacitance of the grid capacitor to which the transverse electrode 200 belongs, either an interruption is produced in the region 202 or an interruption is produced in the region 204. If the
20 interruption is produced in the region 202, then only approximately one third of the transverse electrode 200 is circuitry-effective. By contrast, if an interruption is produced in the region 204, then approximately two thirds of the transverse electrode 200 are circuitry-
25 effective. Through the selection of a region 202 or 204, it is possible to implement corrections of the capacitance of the grid capacitor in the thousandths range.

30 The length of the transverse electrode 200 is 10 micrometers, for example. The width is 0.5 micrometer, for example, so that a process of severing using a laser beam is possible without any difficulty.

35 Figure 4 shows a transverse electrode 220, to which a cutout 222 leads. The cutout 222 extends approximately over the entire length of the transverse electrode 220. As a result, it is possible to interrupt the transverse

electrode 220 at any desired location. In other words, the interruption points can be placed continuously along the longitudinal axis of the transverse electrode 220.

5 In other exemplary embodiments of transverse electrodes 200 and 220, linking regions are used instead of, or in combination with, the regions serving for interruption. The interruption regions and/or the linking regions are arranged either on one transverse electrode of a grid
10 capacitor or on a plurality of transverse electrodes of the grid capacitor.

Figure 5 shows method steps for correcting the capacitance of an integrated capacitor arrangement,
15 e.g. according to figure 1, 2, 3 or 4. In the front end of the method, in a design and simulation stage, the variation of the capacitance of the integrated circuit arrangement around a desired capacitance is determined, for example empirically or on the basis of simulation
20 runs, see method step 300. Correction possibilities are provided depending on the capacitance variations, see method step 302. The correction possibilities are, for example, disconnectable capacitors, connectable capacitors, disconnectable capacitor regions and/or
25 connectable capacitor regions. The correction possibilities are prescribed in method step 302 taking account of the expected capacitance variation such that, with regard to the overall production, the fewest possible interruptions and links have to be produced by
30 heating using the laser beam.

The actual correction method begins in a method step 304, which is followed by the processing of a wafer, see method step 306. By way of example,
35 transistors are produced in a semiconductor material of the wafer. Afterward, metallization layers are applied, capacitors also being produced.

In a method step 308, a measurement is used to detect the actual capacitance of an integrated capacitor arrangement, i.e. in particular the capacitance of the main capacitor 12, 112 together with the capacitances
5 of the disconnectable capacitors 14, 114.

In a subsequent method step 310, the actual capacitance is compared with the desired capacitance. If the actual capacitance is less than or greater than the desired
10 capacitance, in particular less than or greater than a predetermined tolerance range, then method step 310 is directly followed by a method step 312. In method step 312, a check is made to determine whether the actual capacitance is greater than the desired
15 capacitance. If this is the case, then method step 312 is followed by a method step 314, in which interruptions are produced in the integrated capacitor arrangement with the aid of a laser beam, disconnectable capacitors 14, 114 being disconnected from the
20 main capacitor 12, 112. The capacitance of the capacitor arrangement decreases. A disconnection of an electrode section from a transverse electrode is also carried out as an alternative.

By contrast, if it is ascertained in method step 312 that the actual capacitance is less than the desired capacitance, then method step 312 is directly followed by a method step 316. In method step 316, linking regions are heated with the aid of a laser beam. As a
30 result, connectable capacitors 16, 116 are supplementarily connected to the main capacitor 12, 112 or to a main region. The capacitance of the capacitor arrangement thus increases in the direction of the desired capacitance. A connection of electrode sections
35 of a transverse electrode is also carried out as an alternative.

By contrast, if it is ascertained in method step 310 that actual capacitance and desired capacitance match, then a method step 318 follows directly afterward. Method step 318 is also executed after method step 314
5 or method step 316. The wafer is processed further in method step 318. In this case, inter alia, a passivation layer is applied, which closes off the cutouts for the laser beam.

10 In a further method step 320, the circuits arranged on the wafer are singulated and encapsulated in housings. The method is ended in a method step 322.

In another exemplary embodiment, the correction is
15 carried out after the singulation of the circuits. By way of example, current surges are used to heat the interruption regions or the linking regions. The interrogations in method steps 310 and 312 can also be formulated differently.

20

The method specified affords the following advantages:

- the variations in the capacitances caused by geometry or process fluctuations can subsequently be corrected in a simple manner. The yield or the
25 performance can thus be increased.

- The possibility of subsequent correction furthermore allows individual capacitance matching for the respective integrated circuit. Capacitance matching specifically coordinated with other
30 circuit elements can thus be performed, e.g. for the purpose of optimum setting of an operating point. This is advantageous, particularly when the other circuit elements can no longer be corrected.

35 By disconnecting or adding regions of the capacitor with the aid of so-called fuses or antifuses, it is thus possible to subsequently correct the influence of process and geometry fluctuations on the parameters of

the main capacitor, in particular on the capacitance and on the resistance (and thus on the RC constant).

During the correction in method steps 310 to 316, it is possible to use the following formula:

$$C_{corr} = C(0) - \sum_{i=1 \text{ to } I1} C_m(i) + \sum_{n=1 \text{ to } N1} C_p(n),$$

where the quantities used have already been explained above, except for the quantities $I1$ and $N1$. The index i in the summation over the capacitances C_m must take account of all the disconnected capacitors, where $I1$ designates the last disconnected capacitor. The index in the summation over the capacitances C_p must take account of all the connected capacitances, where $N1$ designates the last connected capacitor. Furthermore, it must be taken into consideration that either capacitors are connected or disconnected.

If the capacitances C_m and C_p are identical, then it is possible, instead of the sum, to effect multiplication by a factor specifying the number of disconnected capacitors or connected capacitors.

In the determination of the capacitance variation, it is possible to use the following relationships applicable to a plate capacitor:

$$C = \epsilon_0 \cdot \epsilon_r \cdot A_{eff} / D_{eff},$$

where ϵ_0 , ϵ_r represent the corresponding dielectric constants, A_{eff} represents the effective electrode area and D_{eff} represents the effective distance between electrodes. A fluctuation in the area ΔA_{eff} or in the distance ΔD_{eff} then causes a change in the capacitance of:

$$\Delta C = \Delta A_{eff} / A_{eff} \text{ or } \Delta C = \Delta D_{eff} / D_{eff}.$$

fluctuations, RIE patterning (Reactive Ion Etching) with the use of aluminum or by trench etching with the use of copper. Further causes are fluctuations in the electrode area due to variation of the interconnect thickness or due to CMP fluctuations (Chemical Mechanical Polishing), so-called dishing, non-right-angled trench profile with the use of copper or due to inhomogeneous deposition rates.

- 10 In MIM capacitors and sandwich capacitors, the capacitance is corrected by direct disconnection or connection of M area segments of the electrode:

$$A = A_0 \pm \sum_{i=1}^M A_i,$$

15 where A_0 is the electrode basic area that can no longer be corrected, M is a natural number and A_i is the disconnectable or connectable discrete area elements. The minus sign applies to the disconnectable area elements. The plus sign applies to the connectable area elements.

In the grid capacitors, the electrode area A is set by way of the length L of the interconnect: $A = L \cdot T$, where T is the mean interconnect thickness within the capacitor structure. Through disconnection or connection of M interconnect segments, e.g. n discrete segments L_i of the electrode, correction is effected as follows:

30

$$L = L_0 \pm \sum_{i=1}^M L_i.$$

where L_0 denotes the electrode basic length that can no longer be corrected, M denotes a natural number and L_i denotes the disconnectable or connectable discrete interconnect segments. The minus sign applies to the disconnectable interconnect segments. The plus sign applies to the connectable interconnect segments.

Patent claims

1. A set of integrated capacitor arrangements (10),
5 having at least two integrated capacitor arrangements (10), which have been produced in accordance with identical geometrical designs and which each contain a circuitry-effective main capacitor (12) and at least one correction capacitor (16),
10 having an electrically conductive connection between the correction capacitor and the main capacitor in one capacitor arrangement, the connection having been produced after the production of the main capacitor of
15 this capacitor arrangement,

and having an electrically insulating interruption (62) between the same correction capacitor (16) and the main capacitor (12) in the other capacitor arrangement (10),
20 the interruption having been produced in accordance with the geometrical designs.
2. The capacitor arrangements (10) as claimed in claim 1, **wherein** the connection and the interruption
25 are situated at identical positions in the capacitor arrangements (10).
3. The capacitor arrangements (10) as claimed in claim 1 or 2, **wherein** the connection has been produced
30 by local heating,

and/or **wherein** the connection contains a material warpage which penetrates through a dielectric and arose on account of the heating.
35
4. The capacitor arrangements (10) as claimed in one of the preceding claims, **wherein** a material covering

the connection contains a cutout leading to the connection,

wherein a material covering the interruption (62)
5 contains a cutout (58) leading to the interruption,

and/or **wherein** the cutouts are filled with a passivating material.

10 5. The capacitor arrangements (10) as claimed in one of the preceding claims, **characterized** by in each case at least one further correction capacitor (14),

by a further electrically conductive connection (42)
15 between the further correction capacitor and the main capacitor (12) in one capacitor arrangement (10), the connection having been produced in accordance with the geometrical designs,

20 and with a further electrically insulating interruption between the same further correction capacitor and the main capacitor in the other capacitor arrangement, the interruption having been produced after the production of the main capacitor of the other capacitor
25 arrangement.

6. The capacitor arrangements (10) as claimed in claim 5, **wherein** the further interruption arose as a result of local heating and vaporization of an
30 electrically conducting section.

7. The capacitor arrangements (110) as claimed in one of the preceding claims, **wherein** dielectrics of the capacitors (112 to 116) have a thickness which is equal
35 to the thickness of a dielectric between metallization layers in which connection sections of connections to integrated semiconductor components are situated.

8. The capacitor arrangements (110) as claimed in one of the preceding claims, **wherein** the capacitors (112 to 116) have electrodes situated in more than two metallization layers,

5

and/or **wherein** the electrodes are formed in a whole-area or grid-like manner.

9. The capacitor arrangements (10) as claimed in one of the preceding claims, **wherein** dielectrics of the capacitors (12 to 16) have a thickness which is less than the thickness of the dielectric between metallization layers in which connection sections of connections to integrated semiconductor components are situated, preferably less at least by half.

15

10. The capacitor arrangements (10, 110) as claimed in one of the preceding claims, **wherein** the capacitance of a correction capacitor (14, 16; 114, 116) amounts to less than $1/3$, less than $1/10$, less than $1/100$ or less than $1/1000$ of the capacitance of the main capacitor (12, 112).

20

11. A set of integrated grid capacitors (110),

25

having at least two integrated grid capacitors, which are produced in accordance with identical geometrical designs and each contain a plurality of transverse electrodes forming a circuitry-effective main part of the grid capacitor,

30

characterized by at least two (220) correction transverse electrodes arranged at identical positions in the grid capacitors (110) which electrodes have circuitry-effective lengths of different magnitudes,

35

the circuitry-effective length of a correction transverse electrode (200), after the production of the

main part, having been shortened by an electrically insulating interruption (206) and/or by vaporization of part of the correction transverse electrode or having been lengthened by production of an electrically
5 conductive connection.

12. The grid capacitors (110) as claimed in claim 11, **wherein**, in a material covering the correction transverse electrode, there is arranged at least one
10 cutout (206, 208; 222) leading to the correction transverse electrode and/or to a region at which the correction transverse electrode was arranged prior to the vaporization,

15 and/or **wherein** the cutout (206, 208; 222) is filled with a passivating material.

13. The grid capacitors (110) as claimed in claim 12, **wherein** a plurality of cutouts (206, 208) lead to a
20 correction transverse electrode (200),

or **wherein** one cutout which essentially covers the entire region of the original correction transverse electrode leads to a correction transverse electrode
25 (220).

14. The grid capacitors (110) as claimed in one of claims 11 to 13, **characterized** by features of at least one capacitor arrangement as claimed in one of claims 1
30 to 10.

Abstract

Set of integrated capacitor arrangements, in particular integrated grid capacitors

An explanation is given of, inter alia, a set of capacitor arrangements each having a circuitry-effective main capacitor (12) and a connectable correction capacitor (16). The connection enables the capacitance of the capacitor arrangement (10) to be corrected.

(Figure 1)

List of reference symbols

10	MIM capacitor arrangement
12	Main capacitor
14	Disconnectable capacitor
16	Connectable capacitor
18, 20, 22	Bottom electrode near the substrate
24, 26, 28	Electrode remote from the substrate
30	Contact
32, 34	Interconnect
36, 38	Cutout
40, 42	Region
52, 54	Interconnect
56, 58	Cutout
60, 62	Linking region
La to Lc	Length
C(0), Cm(1), Cp(1)	Capacitance
110	Grid capacitor arrangement
112	Main capacitor
114	Disconnectable capacitor
116	Connectable capacitor
118	Longitudinal electrode
120 to 126	Transverse electrode
128	Longitudinal electrode
130 to 136	Transverse electrode
140 to 146	Longitudinal electrode
150 to 160	Transverse electrode
162	Region
164	Cutout
166	Region
168	Cutout
170, 172	Region
174, 176	Cutout
180, 182	Linking region
184, 186	Cutout
190, 192	Linking region
194, 196	Cutout
200	Transverse electrode

202, 204	Region
206, 208	Cutout
220	Transverse electrode
222	Cutout
300	Determination of the capacitance variation
302	Provide correction possibility
304	Start
306	Wafer processing
308	Detection of the actual capacitance
310	Actual equal to desired?
312	Actual > desired?
314	Interruption
316	Linking
318	Passivation
320	Singulation
322	End
